Warm waters of the epeiric seas facilitated chalk deposition because calcium carbonate is more soluble in cold water rather than warm water, and because organisms that produce calcium carbonate skeletal debris will more actively produce in warm water. More chalk formed during the Cretaceous Period than in any other period in geologic history.

Chalk: A biological limestone formed from shell debris

Monument Rocks is a relatively large, isolated, and weathered outcrop of chalk that preserves rock layers deposited 87-82 million years ago. The rock layers were formed through the accumulation of the remains of untold billions of small, photosynthetic algae called coccolithophores that had skeletons composed of calcium carbonate.

Calcium carbonate is a chemical compound with the formula CaCO3. It is a common substance found in rocks as the minerals calcite and aragonite and is the main component of pearls and the shells of marine organisms, snails, and eggs. Calcium carbonate is the active ingredient in agricultural lime and is created when calcium ions in hard water react with carbonate ions to create limescale. It is medicinally used as a calcium supplement or as an antacid, but excessive consumption can be hazardous a

The Cretaceous as a separate period was first defined by Belgian geologist Jean d'Omalius d'Halloy in 1822, using strata in the Paris Basin and named for the extensive beds of chalk (calcium carbonate deposited by the shells of marine invertebrates, principally coccoliths), found in the upper Cretaceous of Western Europe.

The calcareous sponges of class Calcarea are members of the animal phylum Porifera, the cellular sponges.They are characterized by spicules made out of calcium carbonate in the form of calcite or aragonite.While the spicules in most species have three points, in some species they have either two or four points.

Preservation of dinosaur eggs and footprints by precipitation of calcium carbonate in the Upper Cretaceous Anacleto Formation at Auca Mahuevo, Argentina represents a relatively unusual occurrence in the fossil record. Under normal condition, eggs are readily destroyed in sediments shortly after burial by physical, chemical, and biological processes.

The calcium carbonate is deposited where evaporation of the water leaves a solution that is supersaturated with chemical constituents of calcite. In Yellowstone this sedimentary rock of calcareous sinter forms at the Mammoth Hot Spring Terraces where carbon dioxide-rich water percolates through limestone underground.

Overall, the decline of the CPF in both Eocene and Cretaceous scenarios implies that carbonate ion contributes fractionally less to seawater buffering (borate buffering is fractionally more important), making carbonate ion less sensitive to incremental DIC and ALK perturbation.
